Question 6

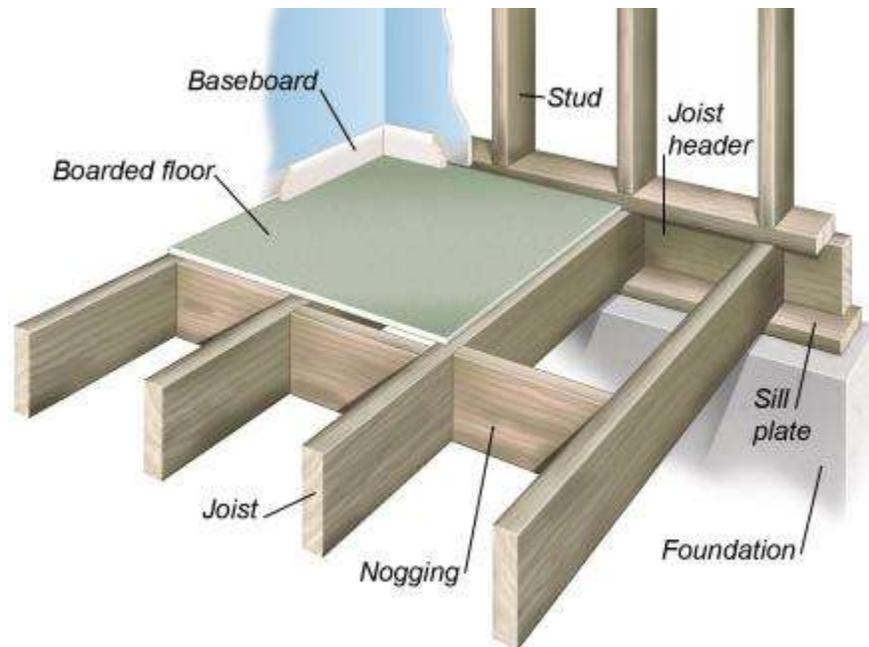

Floor type 1

In this question, the main focus is a two floor, platform system that incorporates joists and bearings with a suitable insulation material. Basically the platform floor system is made of timber and has been used extensively in the construction industry. In its simplest form, the floor is made up of a platform that rests on joists which connect to the joist header and eventually the bearing. As a matter of fact, the members that form this type of a floor include: joists, studs, rafters, plates and framing. All these are the features that make a platform floor.\

As with any other wooden element, fire protection is a necessity and as such, the floors are constructed individually. In the design of an individual platform floor, the bearing system is mainly a foundation from where a sill plate is attached. The support and bearing members are complete when the joist header, attached to the sill plates, connects with the joists. These joists run perpendicular to the joist header and form a base from which the platform can be built. After the design and installment of the joists, a subflooring system is installed on top from where a sole plate may be installed. However, this design of joists has to consider other properties such as insulation. The insulation properties of the platform floor system are affected by effect of joist spacing alongside other factors such as density of the resilient layer and the effect of the absorbing material (Fothergil & Royle, 1991)

The difference in height between the first floor and the next is basically determined by the ceiling height stipulated or required. This difference in height is what determines the studs to be installed. However, the main difference between the ground floor and the upper ones is the fire

stopping requirement of the upper floors whereby the joist hangers provide the necessary fire stopping mechanism necessary.

Platform flooring system

Floor type 2

The second flooring system basically focuses on a concrete floor which can replicate the qualities of the floor on ground. To begin with, there is a very huge difference between the slabs on the ground and those that are not in direct contact with the ground. The former is subjected to ground conditions such as alkalinity, abnormal moisture conditions etc. Therefore, the design of this ground floor slab has to consider extreme soil as well as moisture conditions. Furthermore, this system may be designed according to the type of footing present so as to increase the durability and the ability to withstand aggressive soils.

In the design of the a ground slab, a damp proof membrane is necessary to prevent the soil moisture from having a profound effect on the concrete. However, this may be determined by the

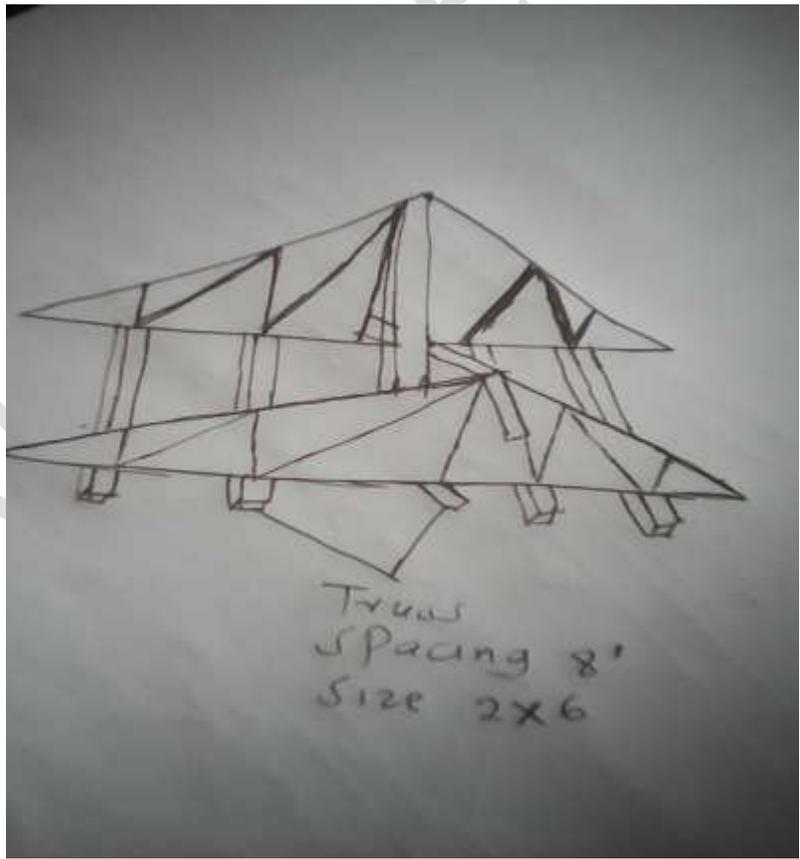

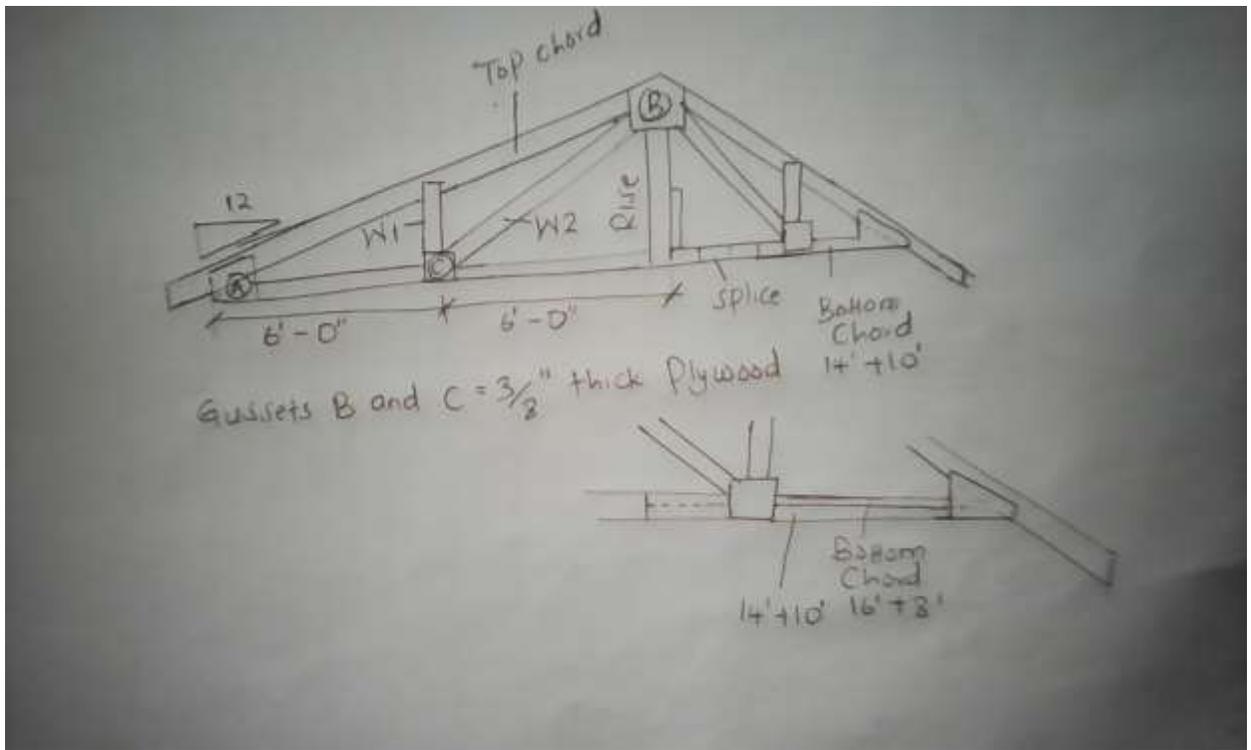

concrete strength chosen and as such, the slabs on the upper floors may require weaker concrete in order to replicate these conditions.

Altering the basic construction principles used in house designs can be used in ensuring that the floor slabs replicate the ground floor conditions. The basic method of construction of slabs is as follows: filling, design of foundations, design of the sloping sites, retaining walls and fixing of the reinforcement. The procedure can be altered in a significant way to ensure that the ground conditions are replicated. Finally, difference in curing and compaction of ground floor concrete and the upper floor concrete can be used to relatively bridge the difference in conditions.

Question 7

One major component of a building is the roofing structure. Prefabricated roof trusses have been extensively used in roof construction because of the relative cheapness and the extensive span coverage. However, the main disadvantage is on the air duct ventilation system and the attic room that can be obtained. In this, it is very difficult to install an air duct system and the attic room is limited.

The basis of this design is based on the assumption that the cottage span is about 7.3152 meters and the make of the trusses is that of a 2 web design. Furthermore, the truss has plywood gussets

Description of the roof truss system used for the design of the span stated above

Roof slope=3/12 which is basically used in areas that have a smaller snow load and for short spans. These are some of the basic design requirements in the cottage design (Midwest plan service).

The 0.6 m truss spacing is selected in this scenario as it is suited for cottage design

Loads to be considered in the design of the truss system

Dead load from ceiling can be estimated as 0.38304kN/m² which basically caters for a ceiling that has insulation properties. As a matter of fact, this type of load is the most common for residential houses and some other simpler forms of commercial buildings (Midwest plan service).

		Truss spacing, feet									Gusset steel in					
Top Bottom	Dead Load	2'			4'			5'			A B C					
		0	5	8	0	5	8	0	5	8	THIN	THIN	THIN			
2x4	2x4	31	33	35	13	0	0	0	0	0	2x4	2x4	2x4	3x5x8-5/16	2x12	2x8
2x4	2x4	56	53	46	24	0	0	12	0	0	2x4	2x4	2x4	3x8x8-1/2	10x12	8x8
2x6	2x4	59	53	52	25	22	19	12	0	0	2x4	2x4	2x4	3x8x8-26	10x12	8x8
2x2	2x6	76	69	65	33	28	25	16	0	0	2x4	2x4	2x4	3x8x8-3/8	12x12	2x8
2x8	4x4	100	100	100	52	46	34	26	0	0	2x4	2x4	2x4	0.31x1.28	14x16	10x10
2x12	4x6	-	-	-	66	58	54	33	27	16	2x4	2x4	2x4	3x8x8-1/2	14x16	10x10
2x12	6x6	-	-	-	67	61	57	33	28	24	2x4	2x4	2x4	3x8x8-5/8	14x16	14x12

Member selection for 3/12 slope

Selection of the member sizes of trusses based on the loads and the spacing(3/12 slope)

Roof framing	
2x4 Purlins, 2.0C	0.7 Psf
2x6 Purlins, 2.0C	1.1 Psf
Ceiling framing	
1x3 furring, 16.0C	0.4 Psf
2x4 furring, 2.0C	0.7
Sheathing, etc.	
1 lumber solid	2.2 psf
1" Plywood	1.1 Psf
0.5" Plywood	1.4 Psf
0.024 Aluminium	0.4 Psf
22 galvanized steel	0.9 Psf
Asphalt Shingles	2.6 Psf
Insulation, for inch 41 thickness	0.1-0.4 Psf

Weight of roofing and ceiling material

The roof loads for the structure (ceiling and roofing)

In this design, the roof framing has been assumed to be made up of 2*4 purlins and as such, imposes a dead load of 0.0336 kN/m². On the other hand, the ceiling framing has been taken to have the dimensions of 1 and 3 while the sheathing is that of galvanized steel. The total dead load for the roofing structure can therefore be estimated by adding all the individual components and as such, the total dead load that the structure has to accommodate=0.075kn/m².

The wind fasteners required for the truss system can be estimated from the table below

Truss span	Truss Spacing		
	2'	4'	8'
20' - 24'	1A or 1B	1A or 1B	2A or 1B
26' - 30'	1A or 1B	1A or 1B	2A or 2B
32' - 46'	1A or 1B	2A or 1B	3A or 2B
48' - 50'	1A or 1B	2A or 1B	4A or 2B
52' - 60'	1A or 1B	2A or 2B	4A or 3B

Wind fasteners that caters for the wind loads subjected to the truss system.

As per our truss system which has a span of about 20-24 feet and a spacing of about 8 feet, the wind bracing used is that of 2 metal framing anchors or 1 ,0.5 inches bolt.

In the design of a truss system, there are two basic systems: the cut off and the prefabricated type. In this, the cut-off system is assembled on site while the prefabricated is delivered to the site with the only work required the installation. Therefore, the prefabricated mode ensures that the cost of labor are at a minimal.

The factors influencing the design of the truss system are: the loads, slope and the distance between trusses. To begin with, the load influences the truss design because of the clear space that can be provided by the trusses upon completion of the design. They are therefore suitable for design of railroads, opera houses etc. Furthermore, they can accommodate a variety of loads such as snow, dead loads wind loads etc. Most of the areas in the world require that that a slope of less

than 25 degrees be used for loads that are greater than 50 pounds/square foot of roof area while those that have a greater slope required to support larger loads (Midwest plan service). The slope influences the stability and as such, decrease in the slope reduces the stability consequently requiring lesser loads.

The slope of the roof basically influences the chord design and as such, some of the rules that have been stipulated for the design of any truss system in relation to the truss slope is that, when shingles are used, the slope should not be less than 50 %. However, this slope is suitable for slate design. Finally, the span affects the design of any house because it basically affects the exterior design. As in our case where the span is about 24 feet, the truss design may be as per the architectural design or may have an effect on the exterior looks of the building
